

THE LANCET

Supplementary appendix

This appendix formed part of the original submission and has been peer reviewed. We post it as supplied by the authors.

Supplement to: Golding N, Burstein R, Longbottom J, et al. Mapping under-5 and neonatal mortality in Africa, 2000–15: a baseline analysis for the Sustainable Development Goals. *Lancet* 2017; published online Sept 25. [http://dx.doi.org/10.1016/S0140-6736\(17\)31758-0](http://dx.doi.org/10.1016/S0140-6736(17)31758-0).

Methods appendix to Mapping under-5 and neonatal mortality in Africa, 2000–2015: a baseline analysis for the Sustainable Development Goals

This appendix provides further methodological detail, including several supplemental figures and tables, for “Mapping under-5 and neonatal mortality in Africa, 2000–2015: a baseline analysis for the Sustainable Development Goals”.

Table of Contents

1. GATHER Checklist	5
2. Geographic Inclusion	6
3. Mortality data sources	7
4. Data outliers	22
5. Tabulating CBH data	22
6. Adjustment of summary birth history data	24
6.1 Data preparation.....	26
6.2 SBH adjustment models	26
6.2.1 Model fits of SBH adjustment models.....	27
6.3 Out of sample validation of SBH Adjustment Model	30
6.4 Inverse-variance weighting of SBH observations	31
7. Applying GBD bias correction	31
8. Spatial integration over polygon records	32
9. Raw data plots	32
10. Covariates and covariate transformation.....	38
10.1 Covariates	38
10.2 Covariate selection and transformation with stacking	39
11. Geostatistical model.....	41
11.1 Model Geographies	41
11.2 Model description	41
11.3 Priors	42
11.4 Model fitting	42
11.5 Model Results	42
11.6 Model validation	46
11.6.1 Spatial aggregation.....	47
11.6.2 Metrics of predictive validity	47
12. Calibration to national estimates.....	50
13. Verification and comparison against other subnational child mortality models	51
13.1 Gavi Full Country Evaluation small area estimates.....	51
13.2 GBD 2015 subnational estimates in Kenya and South Africa	52
14. Source code.....	53
References	53

1. GATHER Checklist

Item #	Checklist item	Reference
Objectives and funding		
1	Define the indicator(s), populations (including age, sex, and geographic entities), and time period(s) for which estimates were made.	Main text (Methods)
2	List the funding sources for the work.	Main text (Acknowledgements)
Data Inputs		
<i>For all data inputs from multiple sources that are synthesized as part of the study:</i>		
3	Describe how the data were identified and how the data were accessed.	Main text (Methods)
4	Specify the inclusion and exclusion criteria. Identify all ad-hoc exclusions.	Main text (Methods); Methods appendix (Sections 2 and 4)
5	Provide information on all included data sources and their main characteristics. For each data source used, report reference information or contact name/institution, population represented, data collection method, year(s) of data collection, sex and age range, diagnostic criteria or measurement method, and sample size, as relevant.	Methods appendix (Supplementary Table 1) and available through ghdx.healthdata.org/
6	Identify and describe any categories of input data that have potentially important biases (e.g., based on characteristics listed in item 5).	Main text (Methods); Methods appendix (Section 6)
<i>For data inputs that contribute to the analysis but were not synthesized as part of the study:</i>		
7	Describe and give sources for any other data inputs.	Methods appendix (Section 10.1)
<i>For all data inputs:</i>		
8	Provide all data inputs in a file format from which data can be efficiently extracted (e.g., a spreadsheet rather than a PDF), including all relevant meta-data listed in item 5. For any data inputs that cannot be shared because of ethical or legal reasons, such as third-party ownership, provide a contact name or the name of the institution that retains the right to the data.	Available through ghdx.healthdata.org/ or on request
Data analysis		

9	Provide a conceptual overview of the data analysis method. A diagram may be helpful.	Main text (Methods);
10	Provide a detailed description of all steps of the analysis, including mathematical formulae. This description should cover, as relevant, data cleaning, data pre-processing, data adjustments and weighting of data sources, and mathematical or statistical model(s).	Main text (Methods); methods appendix
11	Describe how candidate models were evaluated and how the final model(s) were selected.	Main text (Analysis); methods appendix section 11.6)
12	Provide the results of an evaluation of model performance, if done, as well as the results of any relevant sensitivity analysis.	Main text (Analysis); methods appendix (Supplementary tables 9 and 10, Supplementary Figure 13)
13	Describe methods for calculating uncertainty of the estimates. State which sources of uncertainty were, and were not, accounted for in the uncertainty analysis.	Main text (Analysis); methods appendix (Section 11)
14	State how analytic or statistical source code used to generate estimates can be accessed.	Code is provided in an online repository
Results and Discussion		
15	Provide published estimates in a file format from which data can be efficiently extracted.	Raster files for spatial data and csvs of administrative level 1 and 2 estimates to be made available at ghdx.healthdata.org . PDF tables of administrative level 1 and 2 estimates in appendix.
16	Report a quantitative measure of the uncertainty of the estimates (e.g. uncertainty intervals).	Main text (Results; Figure 4); Appendix (Supplementary figures 13 and 14); Appendix tables
17	Interpret results in light of existing evidence. If updating a previous set of estimates, describe the reasons for changes in estimates.	Main text (Research in Context)
18	Discuss limitations of the estimates. Include a discussion of any modelling assumptions or data limitations that affect interpretation of the estimates.	Main text (Limitations)

2. Geographic Inclusion

This analysis aimed to provide high-resolution under-5 and neonatal mortality rate maps across 46 countries in Africa considered among priority countries for monitoring child mortality by the Countdown to 2015 for

Maternal, Newborn, and Child Survival.¹ To this list we added Namibia so that the resulting maps also had continuous coverage of sub-Saharan Africa, a region over which mortality rates and other development metrics are often aggregated.

It was not possible to extend the analysis to include Algeria, Tunisia, Libya, or Western Sahara due to a lack of subnational mortality data from these countries. Cape Verde, Comoros, Mauritius, and São Tomé and Príncipe are each geographically isolated from included countries and cover very small geographic areas, so including these countries in the analysis would provide little advance over existing national estimates. The map of 46 included countries is shown in Supplementary Figure 1.

Supplementary Figure 1. Countries included in mapping under-5 and neonatal mortality rates.

3. Mortality data sources

Supplementary Table 1. Sources of mortality data used in the model. The datasets and reports from which complete birth history (CBH) and summary birth history (SBH) were extracted for each country are detailed under Citation, and the institutions that provided these data are given under Source. Further details are given marked for those sources labelled † as follows: ICF International. 2004-2012. Demographic Health Surveys (various). Calverton, Maryland: ICF International, 2012. CBH surveys marked with * included both

CBH and SBH data and were used in the SBH adjustment model described in section 6. Admin = Administrative level

4. Data outliers

Several surveys were identified for inclusion but were ultimately excluded from the final analysis for concerns about data quality. The 2007 Ethiopia census² was dropped due to 80% missingness in SBH data and unrealistic geographic distribution of mortality risk. A CBH dataset was dropped if the percent of children who died missing either birth or death date exceeded 10%, or exceeded 5% and had reported data quality issues. Such surveys were South Africa NIDS 2011, subnational MICS surveys from Kenyan counties Bungoma, Turkana, Kakamega (2013-2014), and Somalia NE Zone (2011), and the Djibouti PAPFAM survey 2012. Finally, we dropped data points from Diffa region (2012 Niger DHS) and Jonglei and Unity states (South Sudan 2010 MICS) as they were highly discordant with data points from the same surveys in nearby regions with similar sociodemographic profiles.

5. Tabulating CBH data

For each survey cluster we tabulated monthly exposures and deaths for each of four age bins over four separate five-year periods, as illustrated in Supplementary Figure 2. This tabulation process is similar to that used to compute under-5 mortality estimates for GBD 2016.³ The exception to this is that we use four component bins: month 0, months 1-11, months 12-35, and months 36–59, whereas GBD uses six bins: 0 months, 1–11 months, 12–23 months, 24–36 months, 36–47 months, and 48–59 months. For areas larger than survey clusters, survey weights were used in the tabulation step to make weighted mortality rates for each of the component bins, which were then applied to the observed tabulated exposure months to estimate an equivalent number of deaths. Estimates for the 2015 period may be slightly overestimated due to the relatively smaller amount of data in the later years of the period.

Supplementary Figure 2: Lexis diagram illustrating periods and age bins within which CBH data were tabulated. For each month (grey parallelograms) within each age bin/period pair, (rectangles bounded by solid black lines) we tabulated the number of exposures (number of children alive and entering the month of life within the given period) and number of deaths (exposures who died during that month) for each survey cluster, or geographic area comprising multiple clusters, where cluster-specific data were unavailable. For example, if we observed a living child who was 3.5 years old in a January 2004 survey, their life history would be represented with the red line in the figure, extending back to midway through 2001 when they were born. This child would have contributed exposure months in the cells (month/period combinations) crossed by their life history: (age bin 4/period 2005: 6 months; 3/2005: 18 months; 3/2000: 6 months; 2/2000: 12 months; and 1/2000, 1 month). If the same child had died at age 3.5 in January 2004, they would have contributed the same number of exposure months, but also a death event in age bin 4/period 2005.

6. Adjustment of summary birth history data

In a summary birth history (SBH) survey module, a woman is asked a minimum of two questions: the number of children ever born (CEB) to them and the number of those who have died (CD). While providing much less information than the full account of life histories available in CBH data, SBH is widely available. Of the 235 surveys for which we had microdata, 104 contained only summary birth histories, most notably in many Unicef MICS and census datasets.

To be usable for child mortality estimation, SBH needs to be adjusted such that they are representative of age- and time-specific mortality. This involves an adjustment of the rate as well as localizing the mortality rates in time.⁴ Recent model-based improvements have been made on classical indirect methods⁴⁻⁶ by relating the CBH- and SBH-derived rates from surveys where both are available, along with information on parity and maternal age.⁷

SBH and CBH survey modules capture different information on child births and deaths. For CBH data we can tabulate information for each child to directly estimate deaths and exposure months for any desired age bin and time period, while in SBH, the only mortality data available is the CD/CEB ratio for each mother interviewed. Ultimately, for this analysis, we wish to approximate CBH-style binomial samples from available information in SBH. The strong linear relationship between the logit of the CD/CEB ratio and the logit under-5 probability of death (5q0) has been noted in the past and used as motivation for a model-based approach to adjusting SBH to match CBH data.⁷ In this analysis, we had the added challenge of dealing with data that need to be child-age disaggregated, which has not been well explored in the literature. Using surveys with both SBH and CBH modules, we found evidence that logit of CD/CEB had a strong relationship with the monthly probabilities of death tabulated in our analytical age groups from CBH data. The plots in Supplementary Figure 3 show the bivariate relationships across ages and lag-times between in surveys that collect both CBH and SBH data. These plots give strong motivation that a modelling approach should work for smaller age bins as well.

Supplementary Figure 3: Comparison of SBH and CBH mortality. Using surveys that collect both SBH and CBH mortality data, we find a strong relationship between the logit of the monthly probability of death for all of our analytical age bins, as well as with the full under-5 bin, with the logit of CD/CEB for each survey. The logit of CD/CEB is highly predictive of CBH tabulated age-specific monthly mortality probability going back up to 19 years before the survey. Lines drawn show a linear regression line, with a beta coefficient and R-squared provided. SBH = Summary birth history; CBH = Complete birth history; CD = Children died; CEB = Children ever born.

6.1 Data preparation

First, we collated data on over four million children from 119 datasets (mostly DHS) collected since 1998 (the beginning of our study period) that contain both SBH and CBH data, these are marked with an asterisk on Supplementary table 1. We tabulated the CBH deaths and exposure months at the age-period level as described in the section above. Thus, each survey produced up to 16 rows of data, one for each child age bin (month 0, months 1–11, months 12–35, and months 36–59) and time period bin (centred at 2000, 2005, 2010, 2015), each with the number of CBH-tabulated deaths and exposures and SBH-tabulated CD and CEB for the cluster.

We will refer to the CBH-SBH combined dataset as the training set, and the SBH-only data which we aim to adjust as the prediction dataset. The prediction dataset will be aggregated to the level of the smallest possible geography – either survey cluster or some identifiable administrative unit. We will refer from now on to this smallest geography simply as cluster.

In order to use a logit transformation of the CD/CEB ratio in the modelling step (described in the following subsection), we had to ensure the CD data did not include zeroes since the logit of 0 is negative infinity. To do so, we fitted the following Bayesian hierarchical shrinkage model to adjust death counts in surveys that contained clusters with no deaths recorded:

(1)

$$\begin{aligned} CD_i &\sim \text{Binomial}(q_i, CEB_i) \\ \text{logit}(q_i) &= \alpha + \gamma_i \\ \gamma_i &\sim N(0, \sigma^2) \end{aligned}$$

where i is cluster and γ is a normal independent random effect by cluster. Models were fit separately for each survey. A minimally informative prior, $\log\left(\frac{1}{\sigma^2}\right) \sim \text{loggamma}(1, 0.00005)$, was placed on σ . The effect of this adjustment was extremely small, correlation between original CD and adjusted was greater than 0.9999. We then used \hat{q}_i in place of the CD/CEB ratio in the full SBH adjustment model, described in the next section.

6.2 SBH adjustment models

We developed a two-stage regression model for cross-walking SBH data into age and period bin approximate binomial samples to match the CBH input data. In the first model we estimate \hat{p} , the bin specific monthly probability of death. In the second model we estimate \hat{N} , the number of exposure months in that bin. From these two quantities we then simulate bin-specific deaths \hat{N}^+ . \hat{N} and \hat{N}^+ are used as training data at SBH clusters in the geostatistical model described in detail later in this document. 10,000 \hat{N}^+ draws are simulated from draws taken from the predictive posterior distributions of \hat{N} and \hat{p} and the resulting variance is used to down-weight these observations when fitting the geostatistical model. We describe these models in detail below.

The \hat{p} model was fit to the training set at the survey, age bin, period, and level, and then used to predict to SBH-only data at the smallest identifiable geography.

We fit the following Bayesian hierarchical logistic regression model to the training data:

(2)

$$\begin{aligned}
 N_{s,a,p}^+ &\sim \text{Binomial}(p_{s,a,p}, N_{s,a,p}) \\
 \log(p_{s,a,p}/(1-p_{s,a,p})) &= \beta_0 + \text{logit}(\hat{q}_s) (\beta_1 + \text{Age}\beta_2 + \text{Lag}_{s,p}\beta_3 + \text{Age} * \text{Lag}_{s,p}\beta_4) + \mathbf{X}_{s,a,p}\boldsymbol{\beta}_{fe} + \gamma_s + \gamma_{country} \\
 \gamma_s &\sim N(0, \sigma_s^2) \\
 \gamma_{country} &\sim N(0, \sigma_{country}^2)
 \end{aligned}$$

where $N_{s,a,p}$ are the number of monthly exposures recorded in a survey s , age bin a , and time period p , and $N_{s,a,p}^+$ are the number of deaths resulting from all monthly exposures. $N_{s,a,p}$ and $N_{i,a,p}^+$ both come from direct tabulations of the CBH data. α_0 is a global intercept term. \hat{q}_i is the zero-adjusted CD/CEB ratio described above in equation (1). The logit of CD/CEB is modified by interactions with child age bin, lag, and the interaction of child age bin and lag. Lag represents the number of periods between the survey to time of mortality risk. We further included fixed effects for all individual terms from the interactions as well as for mean maternal age, year, parity ratios between 15-19 and 20-24 year olds, parity ratios between 20-24 and 25-29 year olds, the proportions of mothers in the survey in various maternal age bins (15-19, 20-24, and 25-39), and the number of years of coverage the survey had in the period bin. We represent the values of these fixed effect covariates with the bolded matrix element $\mathbf{X}_{s,a,p}$ and their associated coefficients in the vector $\boldsymbol{\beta}_{fe}$. Survey weights were used to make estimates of the independent variables at areas larger than clusters in the prediction data set.

We fit another model to estimate \hat{N} , the expected number of exposure months of life in each child age, period bin. For this second model, the target of inference was a number and not a ratio, so we chose to fit the model on the training set aggregated to the survey-admin1 level, and thus more similar to numbers seen in the prediction dataset. This model was very similar to the model for \hat{p} described in equation (2) but with several key differences: 1) we fit to $N_{i,a,p}$ using a Poisson likelihood; 2) we used $\log(\text{CEB})$ instead of $\text{logit}(\text{CD}/\text{CEB})$ as the main effect driving the adjustment; 3) we added a fixed effects term for $\log(\text{CD})$ and a random effect on survey-admin1; and 4) we replaced the interaction with lag with an interaction with number of years in the period covered by the survey.

In addition, two prediction set censuses (Zimbabwe 2002, and Zimbabwe 2012) were only available in tabulated form. As such, for these three surveys we trained and predicted slightly modified \hat{p} and \hat{N} models, using proportion of women instead of proportion of mothers fixed effects.

All models were fitted using R-INLA. The following minimally informative priors (<http://www.r-inla.org/models/latent-models>) were used: $\beta \sim N(0, 1000)$, $\log\left(\frac{1}{\sigma^2}\right) \sim \text{loggamma}(1, 0.00005)$.

6.3 Out of sample validation of SBH Adjustment Model

We used five-fold cross validation to test how well these models predicted p and N out-of-sample. Using the two training datasets, we fit each of the models five times, each time holding out the response variable from random subset of one-fifth of the surveys. The plot below shows the out-of-sample fits by child age bin, and the table below shows summary predictive validity metrics for the two models for each child age-year bin.

Supplementary Figure 4. Out of sample fits for SBH adjustment models. SBH = summary birth history. X axis: Out of sample data at from the SBH adjustment model. **Y axis:** observed truth from CBH tabulations. 4A shows out of sample predictions from the p model for monthly probability of death. 4B shows the out of sample predictions from the N model for monthly exposures. Plotted in modelled logit and log scales, respectively. Colours indicate child-age groups. Red line indicates unity. SBH=Summary birth history.

Supplementary Table 4. Out-of-sample predictive validity metrics for SBH adjustment models in probability and exposure month space, respectively. Calculated using five holdout folds.

6.4 Inverse-variance weighting of SBH observations

To account for the fact that the adjusted SBH approximated binomial data points were modelled, we chose to weight SBH observations in the prediction proportionally to the uncertainty in each prediction from the two-stage model. These weights are then used when fitting the full geostatistical model.

For each observation of SBH-only data, we took 10,000 draws from the predictive posterior distributions of \hat{p} and \hat{N} . For each draw m we then simulated \hat{N}^+_m from a binomial distribution with parameters \hat{p}_m and \hat{N}_m , giving us 10,000 corresponding draws of \hat{N}^+ . We then took the weights as the inverse of the ratio of the simulated variance of \hat{N}^+ and the expected binomial variance $E[\hat{N}]E[\hat{p}](1 - E[\hat{p}])$. As defined, the weights represent the proportion of excess variance in these observations induced by the two-stages of N and p modelling.

In 7.2% of our predicted SBH observations, weights exceeded 1 because small N and small monthly death probabilities resulted in 10,000 draws of nearly all zeros. This caused very low variance of observed deaths across the draws (lower than expected) and inflated weights. We view this as a computational issue in managing to capture low binomial variance via simulation in situations where we have high confidence that that the outcome should be 0. Taking more draws from the predictive posterior distributions of \hat{p} and \hat{N} is computationally expensive and for these observations we set the weight to 1. Weights ranged from 0.00013 to 1.0, with 25% falling below 0.36, a median weight of 0.75, and a 75th quantile of 0.91.

7. Applying GBD bias correction

Prior to geostatistical modelling, we adjusted mortality data by applying the bias correction ratios used by Wang and colleagues for GBD 2016.³ Briefly, raw under-5 mortality data may differ due to various source-specific biases, sampling-related or non-sampling, and it is thus desirable to account for them when possible in order to generate a consistent time series of under-5 mortality. To adjust for this, a non-linear mixed effects model with source-type specific fixed effects and source-specific random effects nested within a location was fit by Wang and colleagues.³ In addition, one high-quality reference source is chosen as the reference based on expert opinion and general data quality from specific survey series for each country. In the case of Africa, this is typically complete birth histories from DHS. For all non-reference sources, data are adjusted based on the difference between the combination of source-type fixed effects and source specific random effects between the source of interest and the reference source. The ratio of the unadjusted mortality to the adjusted from the model are thus country-source-year specific. We converted these to

monthly ratios and multiplied the number of deaths in each bin-period-cluster by them for all matching records from non-reference data sources.

8. Spatial integration over polygon records

Supplementary Figure 5, shown below, illustrates the k-means clustering method used to generate spatial integration points for areal mortality estimates. For each geographic area, we extracted a raster layer of population counts with cell area of approximately 5x5 km from an Africa-wide population raster for 2010 from the WorldPop project (panel A).⁸ We then sampled 10,000 point locations with replacement from each area, with sampling probability proportional to cell population, to simulate a random sample of the population of the area (panel B). Finally, we applied k-means clustering to the latitudes and longitudes of these locations, with J clusters, such that there was one cluster per 100 raster cells within each polygon area. For each of the J cluster centres, we computed the integration weight as the proportion of the representative points falling within this cluster (being geographically closer to that cluster centre than any other cluster centre) (panel C). These weighted points (pseudo-clusters, representing areal estimates) are then combined with true geographically referenced clusters to create the dataset to train the geostatistical model.

Supplementary Figure 5: Illustration of k-means clustering for selecting spatial integration points and weights for polygon mortality data, applied to the district of Makonde, Zimbabwe. A) Spatial raster of cell-level population counts (blue cells indicating larger populations), B) locations of 10,000 population-representative point locations (with added spatial jitter for illustrative purposes), C) 11 spatial integration points selected by k-means clustering, with the size of each point proportional to its integration weight.

9. Raw data plots

The plots in Supplementary Figures 6 through 10 show the model input data for the four age bins over time. Monthly probabilities of death are plotted over a 48 x 48 pixel lattice over Africa. Pixels represent average mortality probabilities from points falling within each pixel. Plots are unweighted by sample size and are meant only to give a general idea of data coverage and values.

Supplementary Figure 6: Model input data for age bin 1 (neonatal), values indicate the mean monthly probability of death among clusters in each grid cell.

Supplementary Figure 7: Model input data for age bin 2 (1 – 11 months), values indicate the mean monthly probability of death among clusters in each grid cell.

Supplementary Figure 8: Model input data for age bin 3 (12 – 35 months), values indicate the mean monthly probability of death among clusters in each grid cell.

Supplementary Figure 9: Model input data for age bin 4 (36 – 59 months), values indicate the mean monthly probability of death among clusters in each grid cell.

Supplementary Figure 10: Combined input data for age bins1-4, approximating under-5 mortality.

10. Covariates and covariate transformation

Supplementary Figure 11: Images of spatial covariates used (2015 values shown here). EVI = enhanced vegetation index; LST = land surface temperature; PfPR = *Plasmodium falciparum* parasite rate.

10.2 Covariate selection and transformation with stacking

Stacked generalization/regression, or stacking, is a method of combining (ie, ensembling) multiple predictive models in order to enhance predictive validity relative to a single approach or model^{9,10} and has been shown to be effective for geostatistical exercises.¹¹ In short, a suite of child models are fit using different modelling approaches and then combined, or stacked, by using a secondary learner, or stacker. Our implementation of stacking largely follows the approach described in Bhatt and colleagues.¹¹

Our stacking hierarchy features two levels: a collection of ‘child’ models and a stacker model. Although there are possible other configurations, this direct, two-stage approach was taken because of its simplicity, computational tractability, and previous success.¹¹ The child models used for this study include a generalized additive model, a gradient boost machine (also known as boosted regression trees), and penalized regressions (ridge, lasso, and elastic net). All analyses were performed in R,¹² using the mgcv, dismo, and glmnet packages.

Each child model was fit 5+1 times, where five is the number of folds for out-of-sample cross validation, plus one full data model. Data are divided into five folds and for each fold a given model is fit while leaving out one fold of data and training on the remaining data. The left-out fold subsequently serves as out-of-sample test dataset for prediction. Once the out-of-sample cross-validation process is complete for every fold the child model is then trained on the entire dataset. By the end of this process, each observation has an out-of-sample cross-validated prediction and full-fit prediction for each child model. Both the cross-validated predictions and the full-fit predictions are preserved for the subsequent stacking.

The final stacker model (the geostatistical model described in the next section) is fit using the cross-validated predictions of the child models as covariates. By fitting on the cross-validated predictions we incorporate the generalization capabilities of each child model and otherwise reduce overfitting. If correlations in predictions from a pair of child models exceeded 0.99 we dropped one of the models. In all cases, elastic net and lasso regressions met this threshold of correlation and thus we dropped elastic net. Model correlations are reported in supplementary table 6. Final predictions from the geostatistical model were produced using the full-fit predictions from the constituent child models. Supplementary figure 12 illustrates child model full-fit predictions for each child model for age bin 1 in 2000. Child models were fit separately for each age bin and time period.

Supplementary Figure 12. Plots illustrating child model estimates of mortality for one age bin and year (age bin 1 in 2000). Each of these estimated surfaces is then used as a covariate in the geostatistical model. A. Generalized Additive Model (GAM); B. Boosted Regression Trees (BRT); C. Ridge regression; and D. Lasso regression.

Supplementary Table 6. Pairwise correlations between stacking model fits. Elastic Net was dropped due to high correlation with lasso. * = correlation exceeding 0.99.

Model 1	Model 2	Age Bin 1	Age Bin 2	Age Bin 3	Age Bin 4
GAM	BRT	0.928	0.947	0.947	0.939
GAM	Ridge	0.850	0.956	0.961	0.954

11. Geostatistical model

11.1 Model Geographies

In total, we ran four geostatistical models, one for each age bin.

11.2 Model description

The underlying statistical model, fitted separately for each of the four age bins was a spatially and temporally explicit hierarchical generalised linear regression model for binomial data, using the logit link function:

$$\begin{aligned}
 N_i^+ &\sim \text{Binomial}(p_i, N_i) \\
 \text{logit}(p_i) &= \alpha + \mathbf{X}_i\boldsymbol{\beta} + \epsilon_{GP_i} \\
 \epsilon_{GP} &\sim GP(0, \mathbf{K}_{space} \otimes \mathbf{K}_{time}) \\
 \mathbf{K}_{space} &= (\tau 2^{\nu-1} \Gamma(\nu))^{-1} (\kappa \mathbf{D})^\nu K_\nu(\kappa \mathbf{D}) \\
 \mathbf{K}_{time_{k,l}} &= \rho^{|t_k - t_l|}
 \end{aligned}$$

where N_i are the number of monthly exposures recorded in survey cluster/period i , N_i^+ are the number of deaths resulting from all monthly exposures, p_i is the estimated cluster-level 5-year period mortality probability of death, modelled as a logit-linear function of the global intercept α , cluster-level covariate values \mathbf{X}_i and vector of regression coefficients $\boldsymbol{\beta}$. One fixed effect was included for each of the predictions from the cross-validated ‘child’ stacking models. Spatiotemporally correlated residuals ϵ_{GP} are drawn from a three-dimensional, zero-mean Gaussian process (GP) with covariance matrix constructed as the Kronecker product of a spatial covariance matrix \mathbf{K}_{space} and temporal covariance matrix \mathbf{K}_{time} . \mathbf{K}_{space} was defined by a stationary Matérn covariance function over the Euclidean distance matrix \mathbf{D} between all survey cluster locations, with spatial decay parameter κ , spatial smoothness/complexity parameter ν , precision

parameter τ , modified Bessel function of the second kind K_ν , and Gamma function $\Gamma(\cdot)$. Since this Matérn covariance function is the stationary solution of a stochastic partial differential equation (SPDE), it enables the use of efficient statistical machinery for modelling with SPDEs, as described below. We set the complexity parameter ν to be fixed at 2. \mathbf{K}_{time} was defined by the covariance function corresponding to the discrete-time autoregressive stochastic process of the first order (AR1). The AR1 process is typically defined over a nominal random variable: $x_t = \rho x_{t-1} + N(0, \sigma^2)$ where t indexes time (in our case the period) and ρ (which is constrained such that $|\rho| < 1$) and σ^2 are parameters. When convolving the space and time correlation structures with this definition of the AR1 process, the spatial variance $1/\tau$ and the temporal variance σ^2 would be non-identifiable. We therefore omit σ^2 from our definition above, and represent overall space-time variance via the parameter $1/\tau$.

11.3 Priors

The following minimally informative priors were specified over parameters in all four age bin models: $\alpha \sim N(0, 1000)$, $\beta \sim N(0, 1000)$, $\log((1 + \rho)/(1 - \rho)) \sim N(0, 0.15)$. INLA sets an uncorrelated multivariate normal prior on log-transformations of κ and τ , and by default it determines priors based on the characteristics of the finite elements mesh (described in the section below). We use the default minimally informative priors that INLA suggests which, in our setting, yielded $\theta_1 = \log(\tau) \sim N(0.378, 10)$ and $\theta_2 = \log(\kappa) \sim N(-1.64, 10)$.

11.4 Model fitting

Models were fitted by integrated nested Laplace approximations (INLA) and a stochastic partial differential equation (SPDE) representation of the Gaussian-Markov random field (GMRF) approximation to the GP model,¹⁴ using the INLA R package.¹⁵ The INLA-SPDE approach makes use of the close correspondence between a GMRF defined on a sufficiently dense lattice and a GP, the efficient numerical routines enabled by representing GMRFs as SPDEs, and efficient inference over the parameters of these models using the INLA method. These approximations enable us to carry out full Bayesian inference over the model for a very large dataset, where other inference methods (such as MCMC) would be computationally prohibitive. While the result is an approximation to the model posterior, this approach has been shown to have extremely high accuracy when compared with MCMC in both theoretical and real-world mapping problems.¹⁶ We defined the GMRF on a lattice constructed by constrained, refined Delaunay triangulation within a convex hull no closer than five decimal degrees from the coastline of Africa (including Madagascar). Over land this lattice was constrained to have edge length no greater than 0.35 decimal degrees and over sea no greater than five decimal degrees. This was the densest possible lattice we were able to use over the study area at this time before running into computational issues. These fitted models were then used to generate 1,000 posterior samples each of mapped monthly mortality probability estimates for each of the four age groups by random sampling from the numerical approximation to the joint posterior density of the model parameters. These estimates were combined to estimate the pixel-level (marginal) predictive posterior mean neonatal and under-5 mortality probabilities and prediction uncertainty intervals (0.025% and 0.975%).

11.5 Model Results

Geostatistical model results are presented in the Supplementary Table 7. Spatial Matérn covariance parameters κ and τ have been transformed (as have their lower and upper 95% uncertainty intervals) to be

more interpretable. Range represents the distance in decimal degrees at which point approximately 90% of correlation has decayed, and is taken to be $\sqrt{8}/\kappa$. Nominal variance can be interpreted as the variance at each data point, in logit space, it is calculated as: $4\pi\kappa^2\tau^2$. The auto-regressive correlation coefficient for time, ρ , has not been transformed. Fixed effects include an intercept and the cross-validated predictions from the four included 'child' stacking models.

Supplementary Table 7: Model fits for each age-specific model. BRT = boosted regression trees; GAM = generalized additive model; GP = Gaussian process

	0 – 1 month			1 – 11 months			12 – 35 months			36 – 59 months

The figures below show model prediction surfaces for neonatal and under-5 mortality for the four study periods, as well as surfaces representing the lower (2.5%) and upper (97.5%) uncertainty bounds for each pixel.

Supplementary Figure 13. Mean, lower, and upper uncertainty interval predictions for under-5 mortality (5q0) in 2000, 2005, 2010, and 2015. Uncertainty intervals were taken as the 2.5% and 97.5% quantiles of 1,000 predictive draws for each pixel.

Supplementary Figure 14. Mean, lower, and upper uncertainty interval predictions for neonatal mortality in 2000, 2005, 2010, and 2015. Uncertainty intervals were taken as the 2.5% and 97.5% quantiles of 1,000 predictive draws for each pixel.

Supplementary Table 8 shows the posterior expectation of the deviance $D(\theta) = -2\text{Log}(p(y|\theta))$ for each model. In addition to the full models (described above), we ran a ‘null’ model, which only included an intercept and the spatiotemporal random effect. The relative differences of these deviances show how much additional information, at minimum, was gained by including covariates. Across all models the percent difference in deviance between the full and null model ranged from 0.99% to 1.32%.

Supplementary Table 8. Posterior expectation of the deviance for each model, both full and null, and their relative differences.

Age bin	Deviance		Percent difference
	Full model	Null model	
0 – 1 month	296222.6	300147.3	1.32%
1 – 11 months	339985.2	344045.8	1.19%
12 – 35 month	322265.1	325793.8	1.09%
36 – 59 months	242887.9	245299.5	0.99%

11.6 Model validation

In order to understand how well our model predicts mortality in locations where there are no data, we wish to estimate metrics of out-of-sample predictive validity. These are typically mean error (ME, to indicate level of bias), root-mean-squared error (RMSE, to indicate total variation in errors), correlation, and 95% coverage of the predictive intervals.

Model validation with these particular data presents a unique challenge. For relatively rare binomial data with small sample sizes, there is too much variance in the raw data to accurately assess model fit. In Supplementary Figure 15, we illustrate this using simulated data. Here we show that the empirical estimate taken as the ratio of events to observations in simulated binomial data with small p and relatively small N cannot reliably retrieve the probability (true p) they were simulated from. This means that even if we modelled mortality perfectly, we may not know it because many of our sample sizes are so small relative to the mortality proportion we are trying to estimate. The plot on the left shows this experiment done with $N=100$ (plus or minus some noise) and the plot on the right shows the same done with $N=500$ (plus or minus some noise). Adding sample size decreases variance in the empirical estimates, allowing for validation to be done. Many of our clusters are small, with median CBH clusters at 15, 150, 298, and 268 months for age bins 1 through 4, respectively. Furthermore, the monthly mortality probabilities which we estimate, particularly for age bins 3 and 4 are typically well below 0.001.

Supplementary Figure 15. Illustration of sample size impact on the ability to retrieve true probability from empirical binomial estimates.

11.6.1 Spatial aggregation

We chose to aggregate spatially proximal data points within administrative 1 and 2 areas to stabilize estimates of model predictive validity. This offers several benefits: 1) points close to each other should be more similar, and thus if we hold out points randomly in space we will likely inflate metrics of predictive validity because we would have predicted them well based on neighboring points; and 2) by aggregating points and thus creating areas of data sparseness in the model fitting, we more closely reflect true data missingness patterns over un-sampled administrative areas. At the same time it is important to note that choice of aggregation level can be somewhat arbitrary and model fit will generally improve with larger sample sizes at larger areas of aggregation, and different administrative levels will have varying sample sizes.

To predict out of sample, stacking and geostatistical models are run five times for each age bin, each time holding out data assigned to each respective fold. All data points were assigned identified membership within a given administrative unit area. Each administrative area was then randomly assigned a fold. This was done for both level 1 and 2 administrative areas. Once each model had run, we calculated ME, RMSE, correlation, and 95% coverage for the data we held out. We aggregated predictions and data estimates at each administrative unit by taking weighted aggregates based on sample size adjusted for integration and SBH-adjustment weights. RMSE, ME, and correlation were calculated by comparing mean aggregated estimates and predictions across administrative units, weighted on the aggregated sample size at each unit. Coverage was calculated by simulating predictions of child deaths from posterior draws of probability of death and observed sample sizes at each cluster location, thus representing our ability to reproduce hold out data within the specified level of certainty.

11.6.2 Metrics of predictive validity

The tables below show how each model performed based on the metrics of bias, total variance, and coverage. Tables are shown for first administrative unit-level predictions (Supplementary Table 9), and second administrative unit-level predictions (Supplementary Table 10). The number of data points and exposure months in a given holdout area could vary greatly, and validation metrics will be sensitive to this.

Supplementary Table 9. Out-of-sample predictive validity for first administrative-level holdout predictions

Age Bin	Avg estimated monthly probability	Mean Exposure months	Mean Error	RMSE	Correlation	95% Coverage
0-1 month	0.0328	783	-0.0003	0.0058	0.8111	95.0%
1-11 months	0.0031	8134	0.0000	0.0006	0.9043	95.3%
12-35 month	0.0013	16640	0.0000	0.0003	0.9432	92.7%
36-59 months	0.0006	17180	0.0000	0.0002	0.8989	93.8%

Supplementary Table 10. Out-of-sample predictive validity for second administrative-level holdout predictions

Age Bin	Avg estimated monthly probability	Mean Exposure months	Mean Error	RMSE	Correlation	95% Coverage
0-1 month	0.0327	104	-0.0002	0.0107	0.6236	95.1%
1-11 months	0.0031	1110	0.0000	0.0011	0.8017	95.5%
12-35 month	0.0013	2342	0.0000	0.0005	0.8670	93.5%
36-59 months	0.0006	2446	0.0000	0.0003	0.7766	94.4%

Supplementary Figure 16. Data estimates for aggregated administrative 1 level holdouts versus mean out of sample predictions for the same locations. Estimates are taken at each point where there was data in a holdout area and then aggregated weighted by data sample size. Red lines indicate equivalence.

Supplementary Figure 17. Data estimates for aggregated administrative 1 level holdouts versus mean out of sample predictions for the same locations. Estimates are taken at each point where there was data in a holdout area and then aggregated weighted by data sample size. Red lines indicate equivalence.

Predictive agreement in the most recent time period was more difficult to assess because all survey data from this time period (2012-2017) included only data with partial period coverage, and thus smaller sample sizes than the previous time periods. As more data become available for future iterations of this work, we expect these predictions to improve.

12. Calibration to national estimates

As described in the main methods, we calibrated our mapped mortality rate estimates to match at the national level (or first administrative level where available) with mortality estimates from GBD 2016.³ GBD estimates aggregate a wider pool of mortality data that are only available at a national level, including vital registration data. Supplementary figure 17 shows differences in population-weighted national-level estimates of mortality rates from the uncalibrated maps produced by our geostatistical modelling framework and GBD 2016 estimates for all countries and all four time periods. For each period, the average GBD estimate across the 5-years was used, with exception of the more recent period, for which GBD only makes estimates up to 2016 and thus 2017 was excluded. Maps were scaled to GBD by multiplying each pixel-draw by the ratio of national level GBD estimate to national level geostatistical estimate. National level geospatial estimates generally agreed well with GBD estimates as the median under-5 ratio was 1.01 and neonatal was 1.00 with 95% range of 0.81 and 1.22 and 0.76 and 1.19 respectively. There were some extreme outliers with Botswana in 2015 on the low end (0.33 for child and 0.32 for neonatal), and Madagascar 2015 (1.48 for child) and Central African Republic 2010 (1.40 for neonatal) at the high end.

Supplementary Figure 18. Comparison of nationally aggregated population-weighted geospatial estimates, and GBD estimates for the same years. A) Under-5 mortality estimates. B) Neonatal mortality estimates. Red lines indicate unity. The median ratio between GBD and this study's estimates for under-5 mortality was 1.01 [inter-quartile range (IQR): 0.95, 1.14] and for neonatal mortality 1.00 [IQR 0.93, 1.05]. Red lines indicate equivalence.

13.Verification and comparison against other subnational child mortality models

13.1 Gavi Full Country Evaluation small area estimates

As part of the Gavi Full Country Evaluation (Gavi FCE),¹⁸ evaluation teams produced under-5 mortality estimates for Mozambique, Zambia, Uganda, Chad, and Cameroon. Supplementary Figure 18 (A, B, C, D, and E) shows agreement between aggregated population-weighted estimates from this study with the district level small area estimates of that one.

Supplementary Figure 19 Comparison of district- and county-level aggregated population-weighted geospatial estimates, and Gavi-FCE estimates of under-5 mortality for the same years. A) Mozambique. B) Zambia, C) Uganda, D) Chad, and E) Cameroon. Red lines indicate equivalence.

13.2 GBD 2015 subnational estimates in Kenya and South Africa

GBD 2016 included subnational estimates for Kenyan counties and South African regions. Comparisons are shown in Supplementary Figure 19 (A and B) below.

Supplementary Figure 20. Comparison of subnational aggregated population-weighted geospatial estimates, and GBD estimates of under-5 mortality for the same years. A) Kenyan Counties. B) South African Regions. Red lines indicate equivalence.

Results appendix to Mapping under-5 and neonatal mortality in Africa, 2000–2015: a baseline analysis for the Sustainable Development Goals

This appendix provides additional and more detailed results for “Mapping under-5 and neonatal mortality in Africa, 2000–2015: a baseline analysis for the Sustainable Development Goals”.

Figures and Tables

Supplementary Figure 1. Neonatal mortality rates at the 5x5 km resolution in 2000, 2005, 2010, and 2015.

Supplementary results Figure 2. Neonatal mortality rates at the national, administrative 1, administrative 2, and 5x5 km levels in 2015.

Supplementary results Figure 3. Overlapping population-weighted quartiles of neonatal mortality and relative uncertainty in 2015.

Supplementary results Figure 4. Annualised rates of decline for neonatal mortality from 2000 to 2015 (A); predicted neonatal mortality rates in 2030 based on annualised rates of decline achieved between 2000 and 2015 (B); and rates of decline required to reach the SDG3·2 target for neonatal mortality by 2030 (C).

Supplementary results Table 1. Under-5 mortality estimates for subnational administrative level 1 divisions in Africa, 2000, 2005, 2010, and 2015.

Supplementary results Table 2. Under-5 mortality estimates for subnational administrative levels 1 and 2 divisions in Africa, 2000, 2005, 2010, and 2015.

Supplementary results Table 3. Neonatal mortality estimates for subnational administrative level 1 divisions in Africa, 2000, 2005, 2010, and 2015.

Supplementary results Table 4. Neonatal mortality estimates for subnational administrative levels 1 and 2 in Africa, 2000, 2005, 2010, and 2015.

Supplementary Figure 1. Neonatal mortality rates at the 5x5 km resolution in 2000, 2005, 2010, and 2015. All pixels with a neonatal mortality rate equal to or fewer than 12 deaths per 1,000 livebirths, the SDG3-2 target for neonatal mortality, are coloured purple. Pixels with fewer than ten people and classified as “barren or sparsely vegetated” are coloured in gray. Gray areas with diagonal lines are not included in this analysis. SDG = Sustainable Development Goal. km=kilometre.

Supplementary results Figure 2. Neonatal mortality rates at the national, administrative 1, administrative 2, and 5x5 km levels in 2015. All locations with rate equal to or fewer than 12 deaths per 1,000 livebirths, the SDG3·2 target for neonatal mortality, are coloured purple. Pixels with fewer than ten people and classified as “barren or sparsely vegetated” are coloured in gray. Gray areas with diagonal lines are not included in this analysis. SDG = Sustainable Development Goal. km=kilometre.

Supplementary results Figure 3. Overlapping population-weighted quartiles of neonatal mortality and relative uncertainty in 2015. Neonatal mortality rate quartile cut-points were 20, 26, and 31 deaths per 1,000 livebirths. Relative uncertainty was computed as the ratio of the 95% UIs and under-5 mortality rate for each pixel. Cut-points for uncertainty were 44%, 52%, and 62%. The lowest quartile of mortality is white, and the highest is dark pink. The lowest quartile for uncertainty is white and the highest is blue. These colours overlap such that areas coloured purple have both high neonatal rates and high relative uncertainty. Pixels with fewer than ten people and classified as “barren or sparsely vegetated” are coloured in gray. Gray areas with diagonal lines are not included in this analysis. UIs = uncertainty intervals.

Supplementary results Figure 4. Annualised rates of decline for neonatal mortality from 2000 to 2015 (A); predicted neonatal mortality rates in 2030 based on annualised rates of decline achieved between 2000 and 2015 (B); and rates of decline required to reach the SDG3-2 target for neonatal mortality by 2030 (C). 4.4% is the annualised rate of decline that was equivalent to the pace of progress required to meet MDG4. In (A), pixels coloured blue exceeded this pace from 2000 to 2015, while pixels coloured green to yellow had a slower rate of annualised decline during this time. In (B), pixel-level neonatal mortality rates were predicted for 2030 on the basis of annualised rates of decline achieved from 2000 to 2015. Based on this prediction, pixels for which neonatal mortality rates equaled or were less than 12 deaths per 1,000 livebirths in 2030 are coloured purple. In (C), pixels coloured blue will need to achieve a 4.4% or greater decline per year from 2015 to 2030 to achieve the SDG3-2 target for neonatal mortality (12 deaths per 1,000 livebirths). Pixels coloured green to yellow can meet the SDG3-2 target by 2030 at a pace slower than a 4.4% reduction per year from 2015 to 2030. Pixels with fewer than ten people and classified as “barren or sparsely vegetated” are coloured in gray. Gray areas with diagonal lines are not included in this analysis. MDG = Millennium Development Goal. SDG = Sustainable Development Goal.
